

# Homework Assignment 01

*Belov, Neoral, Sahan, Shulga*

*25.10.2018*

## Data

In this assignment we use a data set “experiment\_data”. The data give the number of dots inside rings with different diameters that a person was able to write during 10 seconds. The data set consisting of 36 observations of 4 variables.

- BLOCK -
- HITS\_SUM - total number of hits;
- DIAMETER - the diameter of the ring in cm, a categorical variable with three levels “1”, “3”, “5”;
- HAND - the hand or hands used to perform the experiment, a categorical variable with three levels, “D” - dominant hand, “N” - non-dominant hand , “B” - both hands;

## Mean values and variances

The following table provides the summary of the data set:

```
## BLOCK      HITS_SUM      DIAMETER HAND
## 1:9  Min.    : 9.00    1:12    B:12
## 2:9  1st Qu.:15.75    3:12    D:12
## 3:9  Median :22.00    5:12    N:12
## 4:9  Mean   :21.75
##      3rd Qu.:26.00
##      Max.   :44.00
```

The following tables provide the mean values

```
##      1      2      3      4
## 19.00000 19.66667 22.00000 26.33333
```

```
##      B      D      N
## 19.00000 25.41667 20.83333
```

```
##      1      3      5
## 14.16667 24.66667 26.41667
```

and variances for each block.

```
##      1      2      3      4
## 30.75 31.00 40.75 100.75
```

```
##      B      D      N
## 29.81818 82.44697 38.69697
```

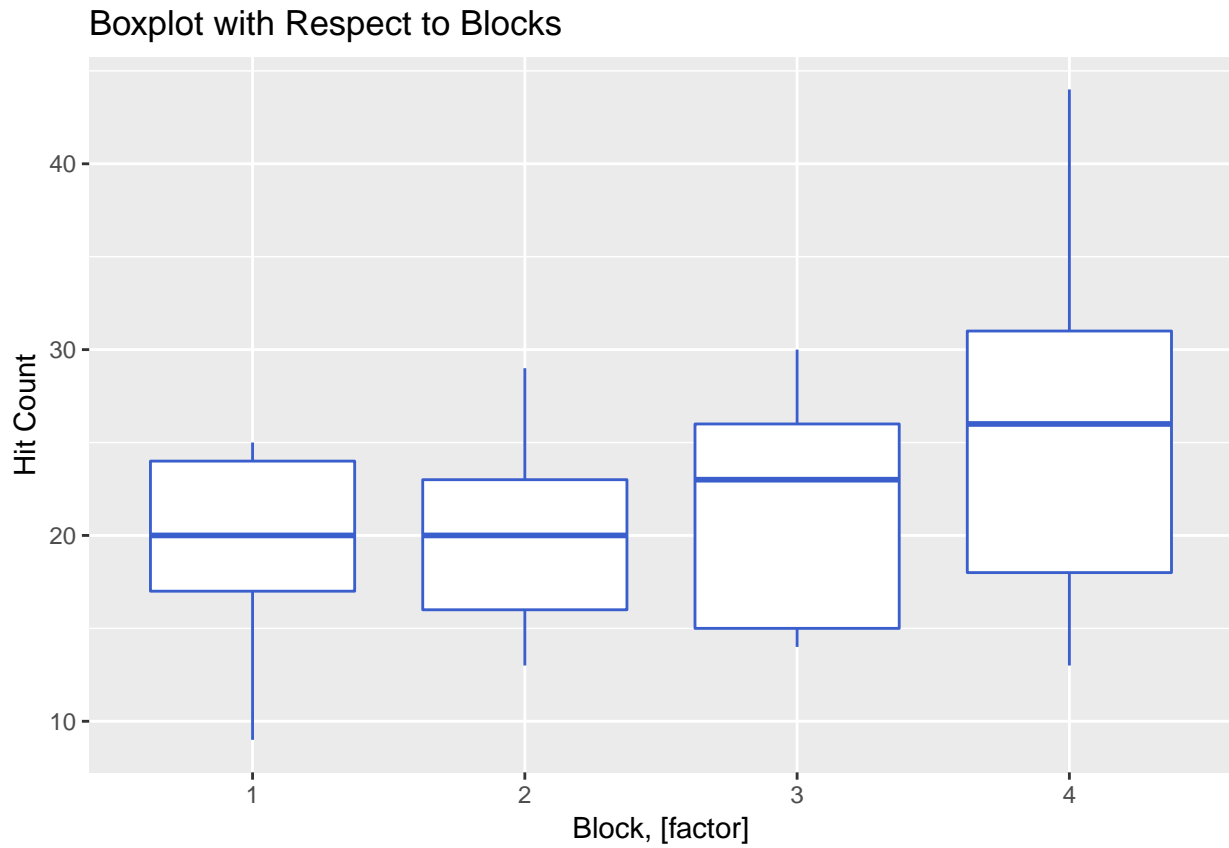

```
##      1      3      5
## 5.424242 20.969697 52.628788
```

We can see that mean values for each of the blocks are slightly different. However, the 4th block shows an outstanding behavior. As a result, further investigation is needed. Regarding circle diameters, the data shows, that with bigger diameter the number of hits increases. Turning to mean values with respect to the hand, as expected, the number of hits made by the dominant hand is significantly larger than that of the

non-dominant and both hands. The variance shows the same behavior as that of mean values. Once again, the 4th block displays outlying behavior performance.

## Data visualization

Let's visualize the dataset using boxplots.

Boxplot with Respect to Hand

Boxplot with Respect to Circle Diameter

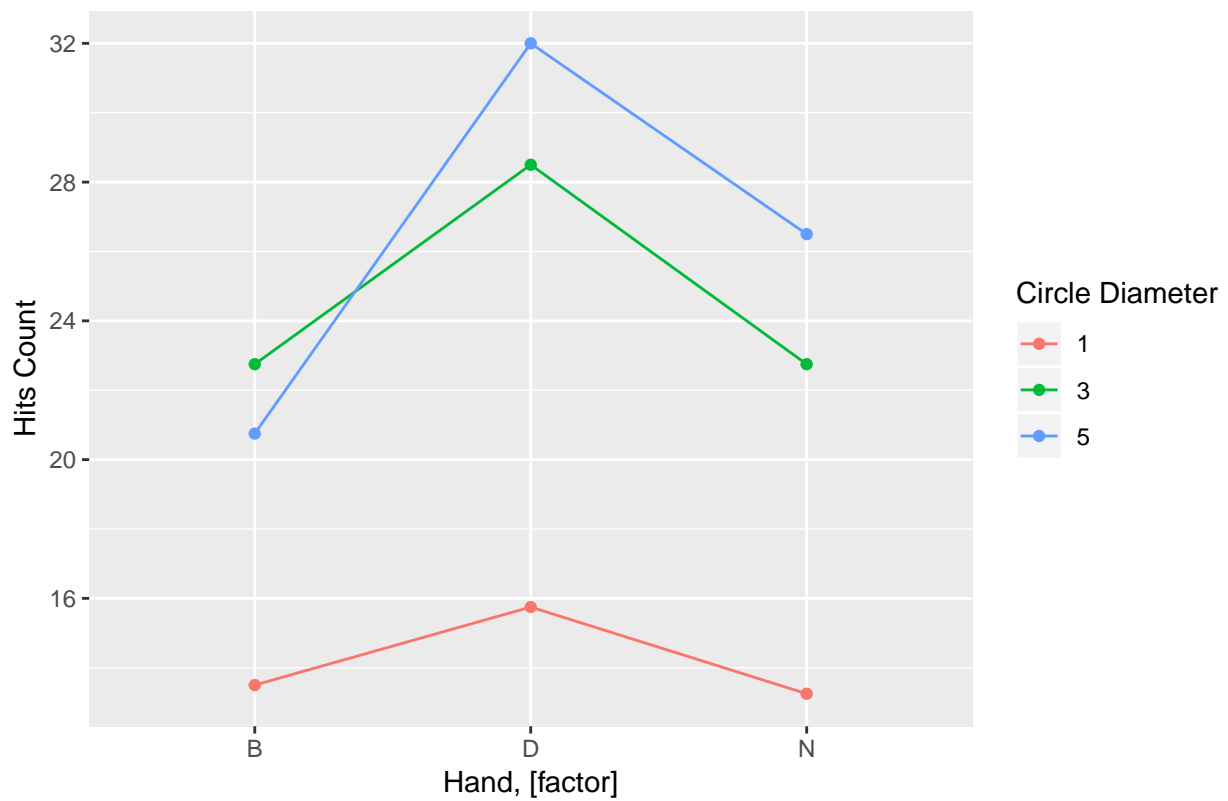

According to the boxplot visualization we can speculate, that mean values are significantly different for the “DIAMETER” variable.

## Interaction plot

Interaction Plot of Hits with Respect to Hand and Circle Diameter

Interaction Plot of Hits with Respect to Hand and Blocks

Interaction plots 1 and 3 display, that the 4th block (operator) is different from the rest. Others show similar ring hits count. This can possibly be caused by the effect of noise. Interaction plot 2 displays the dependence of the ring hits count on the “HAND” and “DIAMETER” variables, e.g. hits count to the ring of diameter 5 cm for the dominant hand is the largest.

## ANOVA without interactions

```
##           Df Sum Sq Mean Sq F value    Pr(>F)
## BLOCK      3  296.8    98.9    8.925 0.000261 ***
## HAND       2  262.2   131.1   11.827 0.000189 ***
## DIAMETER    2 1053.5   526.7   47.526 9.98e-10 ***
## Residuals  28  310.3    11.1
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

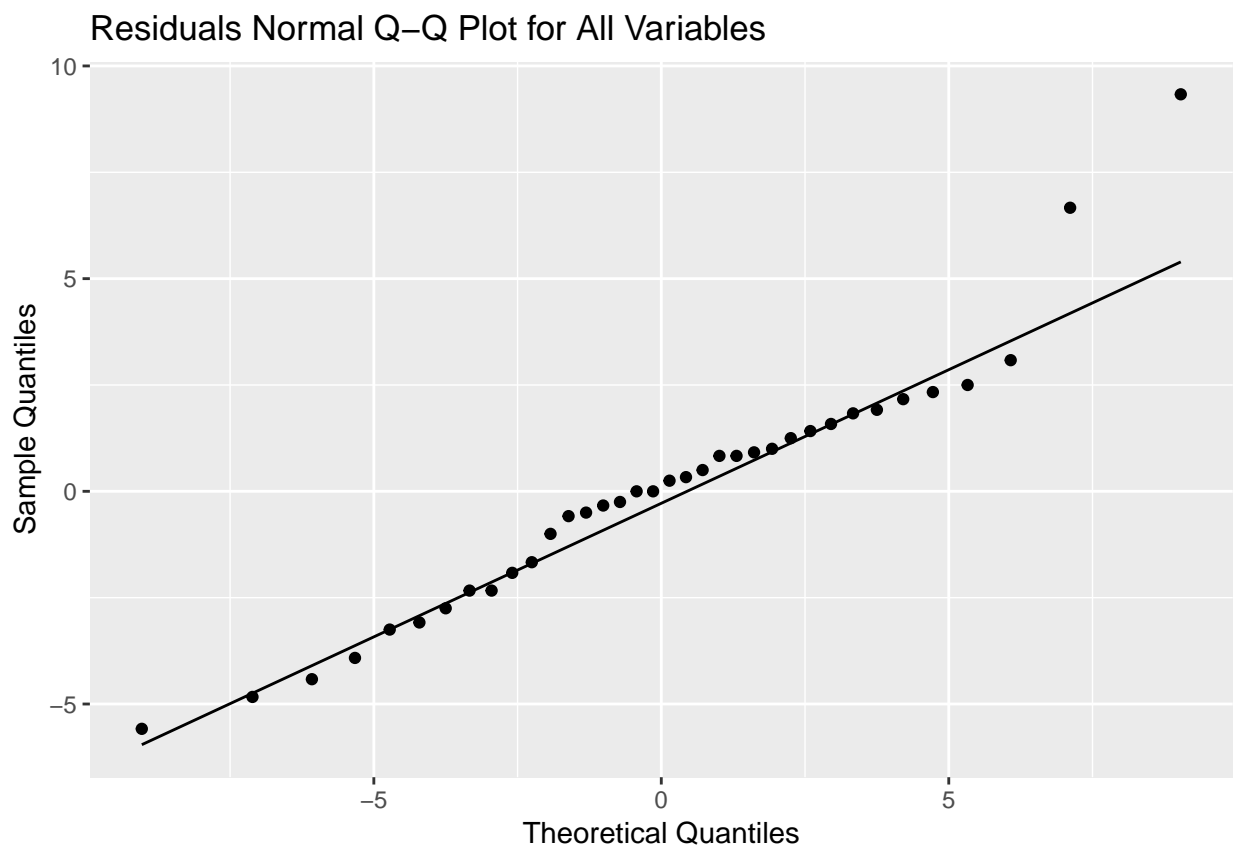

ANOVA has shown, that all variables are significant on the 95% significance level.

```
##           Df Sum Sq Mean Sq F value    Pr(>F)
## HAND       2  262.2   131.1    6.694 0.00383 **
## DIAMETER    2 1053.5   526.8   26.898 1.68e-07 ***
## Residuals  31  607.1    19.6
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

Variables “HAND” and “DIAMETER” are still significant even without dependence of the ring hits on the blocks (operators). That enables us to reject the hypothesis about the equality of mean values.

# Residuals

## Q-Q plot for residuals

Q-Q plots lines fit the data in an acceptable way. However, a few values display outlying behavior. Normality tests must be carried out. We perform Shapiro-Wilk test. The following is the result of the test.

```
##
##  Shapiro-Wilk normality test
##
## data:  residuals_aov_all
## W = 0.94306, p-value = 0.06331
##
##  Shapiro-Wilk normality test
##
## data:  residuals_aov
## W = 0.94531, p-value = 0.07444
```

As p-values from the Shapiro-Wilk test are close to the set significance level (5%), we will also perform the Lilliefors test of normality.

```
##
##  Lilliefors (Kolmogorov-Smirnov) normality test
##
## data:  residuals_aov_all
## D = 0.11724, p-value = 0.2403
##
##  Lilliefors (Kolmogorov-Smirnov) normality test
##
## data:  residuals_aov
## D = 0.12299, p-value = 0.1828
```

As a result of the test, we cannot reject the residuals normality hypothesis for both models.

We perform Fisher's LSD-test,

```
## $statistics
##      MSerror Df  Mean      CV  t.value      LSD
##      11.1  28  21.75  15.31801  2.048407  2.786135

```

Once again, we observe significant difference between the 4th block (operator) and 3 other blocks. An interesting observation is that the 3rd block is on the edge of being significantly similar to the 4th one.

Both tests have confirmed, that the performance of the dominant hand is significantly different from other variants.

Tukey's HSD test and Fisher's LSD test indicate, that rings with diameters 3 cm and 5 cm are significantly similar. On the other hand, the ring with diameter of 1 cm is significantly different from two other ones.
